EES A06: Introduction to Planet Earth

Winter 2019

Professor Nick Eyles

Structure of the course
This course consists of 12 weekly lectures. It involves a mid-term and final exam (each worth 30%) and completion of 10 online modules involving self-assessment questions (40%).

Introduction
Despite what it may appear at times in lectures, this is not a course about motorcycles but is an introductory geoscience course aimed at anyone in the sciences or humanities. If you do like motorcycles so much the better. As a geologist I do a lot of fieldwork in various parts of the globe and I often use two wheels instead of four. If you want to know more about me and what I do I have added a file to go with this course outline. For me life is a journey to see as much of the planet as possible; the idea behind this course is simply to share what I have learned, liked or disliked, with you all in the hope you will begin your own journey.

In this course, you will learn how our planet ‘works’ by virtual visits to countries in very different geologic settings and by meeting some of the peoples that live in dangerous areas affected by earthquakes, tsunamis and volcanic eruptions. We will examine how the planet formed and has evolved in the ancient past, how we determine the age of ancient rocks and events and the nature of changing paleoenvironments on the planet over its long 4.5 billion year history. The course will conclude with a brief review of the geologic history of Canada, the importance of natural resources to our economy, and some of the environmental problems facing our country and world. Simply put, if everyone rode a motorcycle we’d all be better off.
What is geology? Not just rocks

The scientific study of planet Earth is the subject of the discipline called Geology sometimes called Earth Science or Geoscience. The science began as a distinct discipline and profession in Ancient Egypt (may geologic terms are thousands of years old) but became globally important in the early 19th century primarily concerned with finding mineral resources such as coal and metal ores for the Industrial Revolution. It subsequently became a pillar of 19th century science by demonstrating the great age of the Earth (‘deep time’). This thinking underpinned Darwin’s recognition that organisms have evolved through time.

The emphasis on finding scarce resources in a growing and increasingly urban world still continues. Geology is also concerned with exploring Earth history and the history of life on earth, and increasingly dealing with emerging environmental issues especially the impacts of climate change and urbanization and the study of scarce water resources. This is a field called ‘Environmental Geoscience’ which is the focus of a Specialist Undergraduate Program within the Department of Physical and Environmental Sciences (DPES) and a 12 month all-course M.Env.Sc program.

There is a shortage of suitably qualified environmental geoscientists in Canada. The profession requires well-trained individuals and offers many diverse opportunities for a career.

Course content summary

Planet Earth formed about 4.56 billion (000,000,000; abbreviated to Giga annum or Ga) years ago by condensation and accretion of dust and planetary debris. The oldest rocks on Earth are dated at about 4.2 Ga suggesting that continents had already formed. The oldest bacterial life forms occur about 3.5 Ga and an oxygenated atmosphere developed somewhere around 2 Ga before present. Multicellular animal life forms became abundant about 600 million years ago (abbreviated to 600 Ma: mega annum: Ma) an event widely called the ‘Cambrian Explosion.’ The history of life since has been conditioned by episodic extinction events some possibly created by meteorite impacts.

The hard rocky surface of the planet (the crust) is thick (up to 50 km or more), brittle and broken into large pieces called 'lithospheric plates' that are moved around at velocities up to 25 cm/yr by large convection cells in the hotter Earth’s interior (the mantle) below the plates. Alfred Wegener suggested the drift of continents in 1912 but it was rejected as implausible; how could continents move across solid rock below? Today, it is realized that lithospheric plates slide over hot plastic rocks below constantly changing the appearance of the planet by moving continents around, opening and closing ocean basins. This is called plate tectonics and it has been in operation for at least 3.5 Ga. It may not be the only
way in which planet Earth functions however and there is increasing recognition of so-called *vertical tectonics* involving giant mantle plumes of hot rock, and the outpouring of enormous volumes of magma (flood basalts, supervolcanoes etc..) when these plumes reach the Earth’s surface. These are called Large Igneous Provinces (LIPs for short).

Tectonics means ‘to build.’ Lithospheric plates are formed at so-called ‘mid-ocean ridges’ (also called ‘spreading centers’) where new volcanic magma rises to the surface from the underlying mantle and cools to add to the edge of the plate. Continuous addition of new magma and its cooling, results in continuous growth of the plate away and its movement away from the spreading centre (hence its name). This is clearly seen in Iceland today where the mid-Atlantic Ridge is exposed on land and which separates the North American plate from the European plate which are moving in opposite directions away from the spreading center. The North American landmass is part of the plate and it is moving westward; here in Toronto we are moving at 3.7 cm every year. *In the 50 years that UTSC has been in existing it has moved almost 2 m westward from its original position.* Your home is not where it was last night and will be in a different place tomorrow.

The movement of plates leads to collisions between adjoining plates (called *orogeny*) and destruction of some plates by a process called *subduction* where one plate (usually the oldest) is driven down below the other. This is happening along the west coasts of the Americas and around the Pacific and gives rise to large damaging earthquakes and volcanic eruptions. These are called ‘active plate margins.’

The entire plate tectonic process can be likened to a conveyor belt where new crust is created at spreading centres and eventually destroyed by subduction. In this way, the Earth is neither expanding nor shrinking in size. In some cases, orogenic events result in the fusing together of plates (a process called ‘obduction’) and the creation of even larger plates (called supercontinents). Geologists have recognised a cycle of supercontinent formation and breakup (the Wilson cycle) which is the basic rhythm of Earth history.

Much of Canada’s and Ontario’s geology reflects events during the formation and breakup of several supercontinents over the last 3 billion years most notably *Rodinia* which formed about 1 billion years ago and *Pangea* (about 400 to 200 million years ago). Planet Earth is currently in a phase of continent dispersal following the breakup of Pangea when the modern oceans first formed. The formation of the next supercontinent (Pangea II) will occur in another 250 million years’ time. This basic process is driven by convection of hot rock in the deep mantle (fueled by the heat of radioactive decay) and has been modeled to continue for another 4 billion years.
Ancient environments are preserved in the form of rocks and by study of the rock record we can reconstruct ancient paleoenvironments. The concept that the present is the key to the past is called uniformitarianism. Apart from catastrophic events like large meteorite impacts that result in widespread extinctions, the concept has served geologists well.

The course concludes by looking at the 4 billion years long geological history of Canada and Ontario including reference to modern environmental problems facing Canadians. We will look at the causes and impacts of climate change, mineral exploration and mining, the impact of urban development, disposal of a wide variety of wastes, the clean-up of contaminated sites and waters, and the key role that environmental geoscience plays in our society.

At the conclusion of this course you will know how planet Earth ‘works’ regardless of your course of study. This knowledge is the key to protecting our complex human world from risks and natural disasters, the need to protect the environment and to find ever scarcer resources and extract them in an environmentally-sustainable fashion.

Course textbook and other resources

1) The course textbook is Ontario Rocks - Three Billion Years of Environmental Change. It frames the geological history of Ontario against what is known of modern global plate tectonics. Relevant chapters for each lecture are shown on the attached weekly schedule.

2) The course is organized around the supercontinent cycle and a very useful resource is the 5-part Geologic Journey- World series which aired on Canadian Broadcasting Corporation’s ‘The Nature of Things’ in late 2010 with David Suzuki and myself and which is available online. It is based on the geology of various parts of the world and you will need to watch these to supplement lectures.

3) In addition, http://planetrocks.utsc.utoronto.ca is a web site detailing more than 500 hundred sites of special geological or cultural importance across Ontario. Take a look at it.

4) We would also ask you to take a look at Rock Walk outside the Arts and Administration Building to honor the 50th Anniversary of our campus, and which consists of about 50 large boulders of different rock types and accompanying interpretive signage that record changing environments across Ontario over the last 3 billion years. Remember rocks are memories of ancient environments and our only way of knowing what went on millions and billions of years ago.
5) The Atrium of the new Environmental Sciences and Chemistry building has a display consisting of a real time map of global earthquakes. That’s our Earth at work right in front of your eyes.

6) Modules: Each one will be posted on-line on the Monday of the relevant lecture (see schedule). You will have two weeks to review and complete each one. The material will still be available thereafter for exam revision purposes but you will no longer have access to the questions/answers.

https://planetearth.utsc.utoronto.ca
The Plate Tectonic Paradigm (available January 14th to January 27th)
How the Earth Works (available January 21st to February 3rd)
Divergent Boundaries (available January 28th to February 10th)
Convergent Boundaries (available February 25th to March 10th)
Earth Materials (available March 4th to March 17th)
Natural Resources (available March 4th to March 17th)
Canadian Shield (available March 11th to March 24th)
The Paleozoic (available March 18th to March 31st)
Pleistocene Glaciations (available March 18th to March 31st)
The Anthropocene (available April 1st to April 14th)

Evaluation and marks

The course will be evaluated by:

a) **Mid-term exam** (multiple-choice): 30 marks

b) **Completion of 10 online modules**: 40 marks

c) **Final exam** (non-cumulative multiple-choice): 30 marks

You must attend in person to write the mid-term and final exams and there are no deferred exams; if you miss the mid-term other than for medical reasons; in that case all relevant UTSC paperwork must be completed and submitted.
Things to make your life easier (and ours)

1. Please check the Quercus course site regularly for updates and commonly asked Questions and Answers. TAs will be available during regularly-scheduled office hours which will be announced asap.

2. Cheating on online module assessments. This is not something we should have to say but yes folks this stuff happens! And we have a way of finding out too! This issue often arises casually as a result of students wishing to discuss their course work in groups or more problematic is when certain individuals take it upon themselves to compile and circulate answer sheets. Most of you should feel cheated yourselves if a fellow student in the course is taking advantage of YOU in this manner.

So, please do exercise some discretion in filling out answers when you are completing your online module assignments if you are with other students; remember we do investigations of our own. The key point here is that the material will also on the exams so you will need to know the stuff anyway.

Cheating is an academic offence and will be immediately reported to the Dean who will issue appropriate penalties. It happens every year so MAKE SURE IT ISN’T YOU.

3. We don’t bell curve exam marks

4. We don’t know the dates of the mid-term and final exams until we are informed of them: we have no control over when they are so don’t ask

5. We like rocks, motorcycles and the English Premier League (some teams better than others and only those beginning with an A)

6. AccessAbility Services: Students with diverse learning styles and needs are welcome in this course. In particular, if you have a disability/health consideration that may require accommodations, please feel free to approach the AccessAbility Services Office as soon as possible. They will work with you to ensure you can achieve your learning goals in this course. All enquiries are confidential. The UTSC AccessAbility Services staff members are available by appointment to assess specific needs, provide referrals and arrange appropriate accommodations (416-287-7560) or ability@utsc.utoronto.ca.

7. DO NOT EMAIL THE PROFESSOR. There are over 1000 students in this course and we have a well-tried system in place that works to ensure your time with us is worry-free (see # 1 above). It works well so you have no reason to email the Professor. We do welcome feedback and I am available before and after the lecture so come up and introduce yourself.
Enjoy the course and learn something you didn’t know about this wondrous planet that we are lucky to be alive on!

Nick Eyles
