# CSCB63 – Design and Analysis of Data Structures

Anya Tafliovich<sup>1</sup>

<sup>&</sup>lt;sup>1</sup>based on notes by Anna Bretscher and Albert Lai

#### AVL tree

- stores key/value pairs in all nodes (both leaf and internal)
- has a property relating the keys stored in a subtree to the key stored in the parent node (ordering)
- maintains the height (number of edges on a root-to-leaf path) of  $\mathcal{O}(\log n)$ 
  - balance factor = height(left subtree) height(right subtree)
  - maintain balance factor of  $\pm 1$  or 0 for all nodes

#### Operations are $\mathcal{O}(\log n)$ :

- search(k, T): return the value corresponding to key k in the tree T
- insert(k, v, T): insert the new key/value pair k/v into the tree T
- delete(k, T): delete the key/value pair with key k from the tree T

.

### more AVL operations

Given two AVL trees,  $T_1$  and  $T_2$ , create the

- union of  $T_1$  and  $T_2$ 
  - an AVL tree T that contains key/value pairs from T<sub>1</sub> as well as from T<sub>2</sub>
  - if  $(k, v_1) \in T_1$  and  $(k, v_2) \in T_2$ , then decide whether  $(k, v_1) \in T$  or  $(k, v_2) \in T$
- intersection of  $T_1$  and  $T_2$ 
  - an AVL tree T that contains key/value pairs that are in both  $T_1$  and  $T_2$
  - if  $(k, v_1) \in T_1$  and  $(k, v_2) \in T_2$ , then decide whether  $(k, v_1) \in T$  or  $(k, v_2) \in T$
- difference of  $T_1$  and  $T_2$ 
  - an AVL tree T that contains key/value pairs that are in  $T_1$  but not in  $T_2$

#### AVL union

Given two AVL trees,  $T_1$  and  $T_2$ , create the union of  $T_1$  and  $T_2$ :

- an AVL tree T that contains key/value pairs from  $T_1$  as well as from  $T_2$
- if  $(k, v_1) \in T_1$  and  $(k, v_2) \in T_2$ , then we will have  $(k, v_2) \in T$  (update)

#### Simple way to construct the union:

- wlog,  $numnodes(T_1) = n \le m = numnodes(T_2)$
- insert all nodes from  $T_1$  into  $T_2$
- complexity?
- can we do better?

### divide and conquer algorithms

#### Idea:

- split the input into smaller pieces (divide)
  - obtain smaller problems of the same kind
- apply the algorithm to the smaller pieces (conquer)
  - obtain solutions to the smaller problems
- build the answer from the answers to the smaller problems

Some example you have seen before?

#### **AVL** union

Given two AVL trees,  $T_1$  and  $T_2$ , create the union of  $T_1$  and  $T_2$ .

Divide and conquer approach:

- split T<sub>1</sub> into smaller trees
- split  $T_2$  into smaller trees
- build unions of smaller trees
- merge results into union of  $T_1$  and  $T_2$

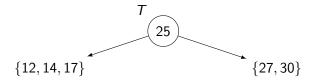

### AVL union: split

- suppose tree  $T_2$  has key k at root node
- split  $T_1$  into  $T_{< k}$  and  $T_{> k}$ , both balanced
  - $T_{< k}$  contains keys from  $T_1$  that are less than k
  - $T_{>k}$  contains keys from  $T_1$  that are bigger than k

• need algorithm split(T, k) that returns ( $T_{< k}$ ,  $T_{> k}$ ) such that both  $T_{< k}$  and  $T_{> k}$  are AVL trees

# AVL union: split

split(T, k) idea

• how to split at key 16?

### AVL union: split

```
split(T, k) algorithm
  if T == nil:
      return (nil, nil)
  if k == T.key:
      return (T.left, T.right)
  if k < T.key:
      (L, R) = split(T.left, k)
      R' = join(R, T.key, T.right)
      return (L, R')
  if k > T.key:
      (L, R) = split(T.right, k)
      L' = join(T.left, T.key, L)
      return (L', R)
```

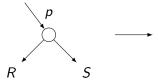

Need algorithm for join!

join(L, k, G) idea

- L already contains keys < k, G already contains keys > k
- if L much taller than G (height(L) height(G) > 1)
  - insert k and G as subtree into L
- if G much taller than L (height(G) height(L) > 1)
  - insert k and L as subtree into G
- if L and G differ by  $\leq 1$  (abs(height(L) height(G))  $\leq 1$ )
  - make a tree with k in root, L as left subtree, and G as right subtree

if height(L) - height(G) > 1, insert G as subtree into L:

- 1. in L, keep going to the right to find the node p such that
  - p is still too tall: height(p) height(G) > 1, but
  - but p.right is just right:  $height(p.right) height(G) \le 1$
- 2. create new node q with key k, left child p.right, and right child G, this node becomes p's new right child
- 3. rebalance from p upwards, as needed

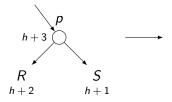

if height(L) - height(G) > 1, insert G as subtree into L.

How do we know the result is an AVL?

- height(p) height(G) > 1, but
- $height(p.right) height(G) \le 1$

Let h = height(G).

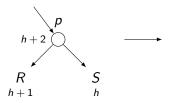

#### Case 1:

- height(p) height(G) > 1, but
- $height(p.right) height(G) \le 1$

Let h = height(G).

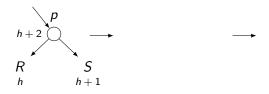

#### Case 2:

- height(p) height(G) > 1, but
- $height(p.right) height(G) \le 1$

Let h = height(G).

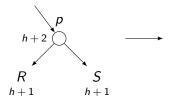

#### Case 3:

- height(p) height(G) > 1, but
- $height(p.right) height(G) \le 1$

Let h = height(G).

#### Case 4:

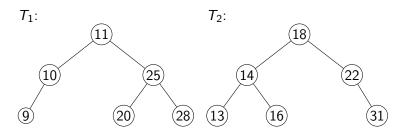

```
join(L, k, G) pseudocode
  if height(L) - height(G) > 1:
    p = L
    while height(p.right) - height(G) > 1:
      p = p.right
    q = new node(key=k, left=p.right, right=G)
    p.right = q
    rebalance and update heights at p up to the root
    return I.
  elif height(G) - height(L) > 1:
    ... symmetrical ...
  else:
    return new node(key=k, left=L, right=G)
```

#### AVL union

```
Finally, union (T_1, T_2) algorithm:
if T_1 == nil:
  return T_2
if T_2 == nil:
  return T_1
k = T_2.key
(L, R) = split(T_1, k)
L' = union(L, T_2.left)
R' = union(R, T_2.right)
return join(L', k, R')
```

### AVL union: example

Follow all the steps of the algorithm above to construct the union of:

Complete example in tutorial.

# AVL union: complexity

• So, did we do better than our first try?

• Best union / intersection / difference algorithm for balanced trees (including AVL and red-black trees) is  $\Theta(n \log(\frac{m}{n} + 1))$  (numnodes( $T_1$ ) =  $n \le m = numnodes(T_2)$ )

 Can find proof of complexity in Guy Blelloch, Daniel Ferizovic, and Yihan Sun, Parallel ordered sets using join. ACM Symposium on Parallelism in Algorithms and Architectures (SPAA), 2016. https://arxiv.org/abs/1602.02120
